데이터 구조 실습

연결리스트, 스택, 큐 이론 및 실습

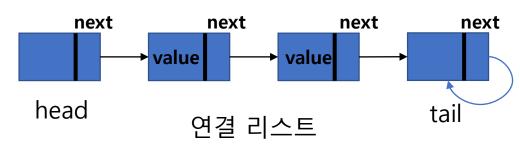

배열과 연결리스트의 차이점

- 배열은 정적인 자료 구조이지만, 연결리스트는 동적인 자료 구조이다.
- 배열은 메모리의 연속된 공간을 차지하는데 비해서 연결 리스트는 메모리의 연속된 공간을 차지하지 못한다.
- 자료의 순서를 마구 바꾸어야 할 경우 배열의 경우에는 당기고 미는 등의 메모리 복사가 필요하지만, 연결 리스트의 경우에는 링크가 가리키는 방향만 바꾸어 주면 된다.

char $a[5] = \{'a', 'b', 'c', 'd', 'e'\};$

각각의 노드들을 연결해줌

연결리스트 구현 코드

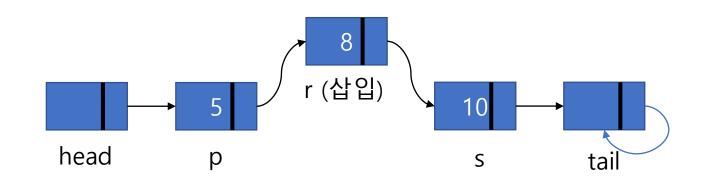

```
- 선언
typedef struct _node {
  int key;
  struct _node *next; // 다음 노드를 가리킬 구조체 포인터
}node;
                // 맨 처음 노드와 맨 마지막 노드(head 와 tail 노드에는 key 값을 넣지 않음)
node *head, *tail;
- 초기화
void init_list(void)
                                                           next
                                                                      next
   head = (node *)malloc(sizeof(node));
   tail = (node *)malloc(sizeof(node));
   head->next = tail;
                                                        head
                                                                    tail
   tail->next = tail;
```

- 크기 순서대로 정렬해서 삽입

```
node *ordered_insert(int k)
    node *s, *p, *r;
    p = head;
    s = p->next;
    while (s->key <= k && s != tail)
        p = p->next;
        s = p->next;
    r = (node *)malloc(sizeof(node));
    r->key = k;
    p->next = r;
    r - \text{>} next = s;
    return r;
```

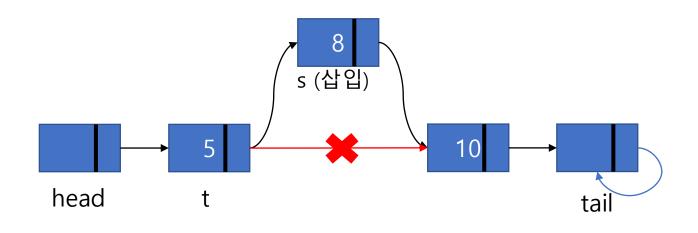

- t 노드 다음에 삽입

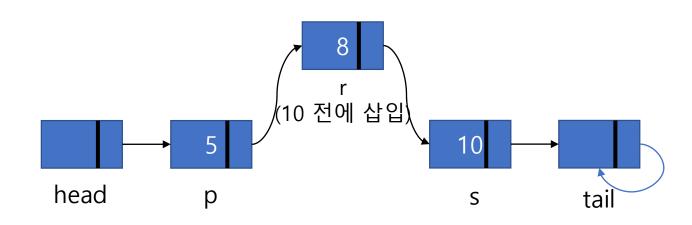

```
node *insert_after(int k, node *t)
{
    node *s;
    s = (node *)malloc(sizeof(node));
    s->key = k;
    s->next = t->next;
    t->next = s;
}
```

- k 전에 t 삽입

```
node *insert_node(int t, int k)// insert t before k
    node *s, *p, *r;
    p = head;
    s = p->next;
    while (s->key != k && s != tail)
        p = p->next;
        s = p->next;
    if (s != tail)
        r = (node *)malloc(sizeof(node));
        r->key = t;
        p->next = r;
        r - \text{>} \text{next} = s;
    return p->next;
```

- 모든 노드 값 출력

```
void print_list(node *t)
{
    printf("₩n");
    while (t != tail)
    {
        printf("%-8d", t->key);
        t = t->next;
    }
}
/* 호출 할 때는 print_list(head->next);
이렇게 호출 하면 head->next 부터 tail 전까지 모든 노드 값들이 출력됨. */
```

- k 값을 가지고 있는 노드 찾기

```
node *find_node(int k)
{
    node *s;
    s = head->next;

    while (s->key != k && s != tail)
        s = s->next;

    return s;
}

/* head->next 노드 부터 시작해서 k값을 찾을 때까지 계속
next로 이동함. k값의 노드 주소를 반환함. */
```

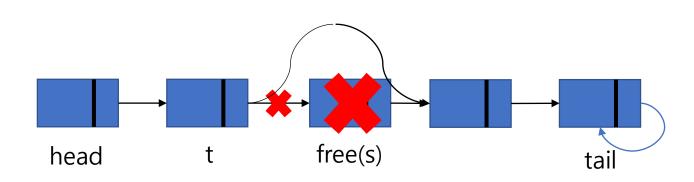

- t 노드의 다음 노드 삭제

```
int delete_next(node *t)
{
    node *s;

    if (t->next == tail) // t 노드의 다음이 tail일 경우 삭제하지 않음 return 0;

    s = t->next;
    t->next = t->next->next;
    free(s);

    return 1;
}
```

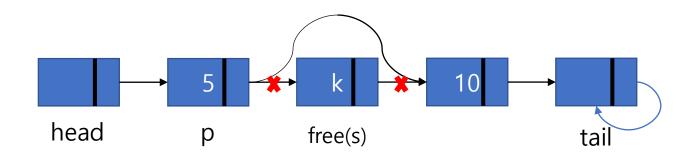

- k 값을 갖는 노드 삭제

```
int delete_node(int k)
   node *s, *p;
   p = head;
   s = p->next;
   while (s->key != k && s != tail)
       p = p->next;
       s = p->next;
   if (s != tail)
       p->next = s->next;
       free(s);
       return 1;
   else
       return 0;
```

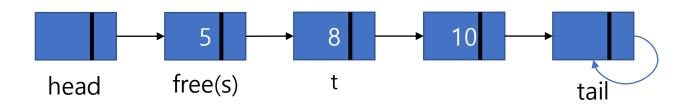

- 모든 노드 삭제

```
node *delete_all(void)
    node *s, *t;
    t = head->next;
   while (t != tail)
        s = t;
        t = t->next;
        free(s);
    head->next = tail;
    return head;
```

스택의 개념

- 밑이 막힌 긴 통(무언가를 넣는 곳과 빼내는 곳이 같음)
- 입, 출구가 같기 때문에 먼저 들어간 것은 밑에 있게 되고 나중에 들어간 것이 위에 있다.
- 결국 제일 나중에 들어간 것이 제일 먼저 나오게 된다. LIFO(Last In First Out) 구조.
- 스택의 조작 방법 (push, pop 동작)

배열로 스택 구현하기!

- 스택 배열, top 변수 및 초기화

```
#define MAX 10

int stack[MAX];

void init_stack(void)
{

}
```

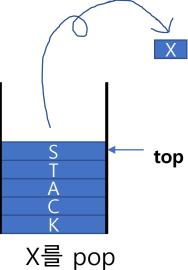

- push, pop 함수 구현

```
int push(int t)
    if (top >= MAX - 1)
        printf("\mathbb{\text{w}}n stack overflow.");
        return -1;
    stack[++top] = t; // 전위 연산자
    return t;
int pop(void)

        printf("\mathbb{\text{W}}n stack underflow.");

연결리스트로 큐 구현하기!

- 큐 초기화

```
typedef struct _dnode{
   int key;
   struct _dnode *prev;
   struct dnode *next;
}dnode;
dnode *front, *rear;
void init_queue(void)
   front = (dnode *)malloc(sizeof(dnode));
    rear = (dnode *)malloc(sizeof(dnode));
   front->prev = front;
   front->next = rear;
    rear->prev = front;
    rear->next = rear;
// put할 때 tail 바로 뒤를 쉽게 찾기 위해 prev 사용
```
