#### 배열과 연결리스트의 차이점

- 배열은 정적인 자료 구조이지만, 연결리스트는 동적인 자료 구조이다.
- 배열은 메모리의 연속된 공간을 차지하는데 비해서 연결 리스트는 메모리의 연속된 공간을 차지하지 못한다.
- 자료의 순서를 마구 바꾸어야 할 경우 배열의 경우에는 당기고 미는 등의 메모리 복사가 필요하지만, 연결 리스트의 경우에는 링크가 가리키는 방향만 바꾸어 주면 된다.

char  $a[5] = \{'a', 'b', 'c', 'd', 'e'\};$ 

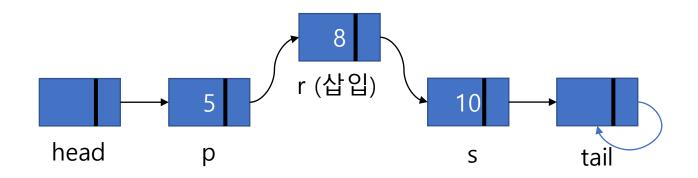

#### 연결리스트 구현 코드

```
- 선언
typedef struct _node {
  int key;
  struct _node *next; // 다음 노드를 가리킬 구조체 포인터
}node;
                // 맨 처음 노드와 맨 마지막 노드(head 와 tail 노드에는 key 값을 넣지 않음)
node *head, *tail;
- 초기화
void init_list(void)
                                                           next
                                                                      next
   head = (node *)malloc(sizeof(node));
   tail = (node *)malloc(sizeof(node));
   head->next = tail;
                                                        head
   tail->next = tail;
```

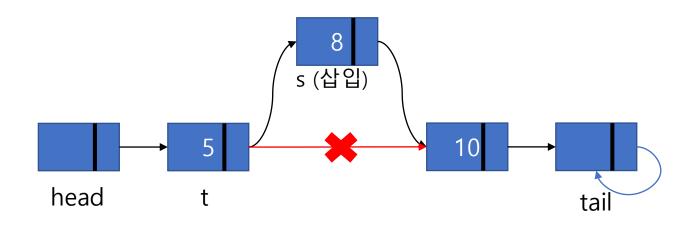

#### - 크기 순서대로 정렬해서 삽입

```
node *ordered_insert(int k)
    node *s, *p, *r;
    p = head;
    s = p->next;
    while (s->key <= k && s != tail)</pre>
        p = p->next;
        s = p->next;
    r = (node *)malloc(sizeof(node));
    r->key = k;
    p->next = r;
    r - \text{next} = s;
    return r;
```

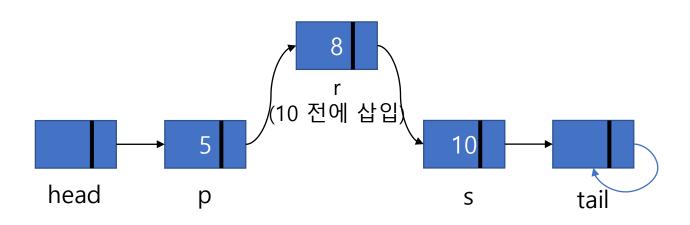

#### - t 노드 다음에 삽입

```
node *insert_after(int k, node *t)
{
    node *s;
    s = (node *)malloc(sizeof(node));
    s->key = k;
    s->next = t->next;
    t->next = s;
}
```

#### - k 전에 t 삽입

```
node *insert_node(int t, int k)// insert t before k
    node *s, *p, *r;
    p = head;
    s = p->next;
    while (s->key != k && s != tail)
        p = p->next;
        s = p->next;
    if (s != tail)
        r = (node *)malloc(sizeof(node));
        r->key = t;
        p->next = r;
        r - \text{>} next = s;
    return p->next;
```

#### - 모든 노드 값 출력

```
void print_list(node *t)
{
    printf("\n");
    while (t != tail)
    {
        printf("\n"-8d", t->key);
        t = t->next;
    }
}

/* 호출 할 때는 print_list(head->next);
이렇게 호출 하면 head->next 부터 tail 전까지 모든 노드 값들이 출력됨. */
```

#### - k 값을 가지고 있는 노드 찾기

```
node *find_node(int k)
{
    node *s;
    s = head->next;

    while (s->key != k && s != tail)
        s = s->next;

    return s;
}

/* head->next 노드 부터 시작해서 k값을 찾을 때까지 계속
next로 이동함. k값의 노드 주소를 반환함. */
```

#### - t 노드의 다음 노드 삭제 int delete\_next(node \*t) node \*s; if (t->next == tail) // t 노드의 다음이 tail일 경우 삭제하지 않음 return 0; s = t->next;t - next = t - next - next;free(s); return 1; head free(s)

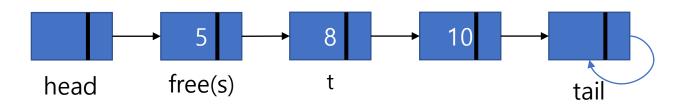

#### - k 값을 갖는 노드 삭제

```
int delete_node(int k)
   node *s, *p;
   p = head;
   s = p->next;
   while (s->key != k && s != tail)
       p = p->next;
       s = p->next;
   if (s != tail)
       p->next = s->next;
       free(s);
       return 1;
   else
       return 0;
```

#### - 모든 노드 삭제

```
node *delete_all(void)
    node *s, *t;
    t = head->next;
   while (t != tail)
        s = t;
        t = t->next;
        free(s);
    head->next = tail;

#### 스택의 개념

- 밑이 막힌 긴 통(무언가를 넣는 곳과 빼내는 곳이 같음)
- 입, 출구가 같기 때문에 먼저 들어간 것은 밑에 있게 되고 나중에 들어간 것이 위에 있다.
- 결국 제일 나중에 들어간 것이 제일 먼저 나오게 된다. LIFO(Last In First Out) 구조.
- 스택의 조작 방법 (push, pop 동작)

#### 배열로 스택 구현하기!

\* 코딩 실습

- 연결리스트로 스택 구현하기에서 main 문에서 호출한 push(), pop(), print\_stack(), clear\_stack() 함수 정의부 직접 작성하기!

push(): head->next 위치에 노드를 삽입하는 함수

pop(): head->next 노드를 빼내는 함수

print\_stack(): 스택 안의 모든 노드의 값들을 top->bottom 순으로 출력하는 함수

clear\_stack(): 스택 안의 모든 노드를 삭제하고 스택을 초기화(head, tail만 남은 상태)하는 함수
